

Short-term memory — QAState fields are the channels nodes use to talk to each other

No separate memory agent/store: every node reads what an earlier node wrote, straight from shared state

Field in QAState	Written by	Read by
query	Node 1 (understand)	Node 2 (search)
evidence	Node 2 (search)	Node 4 (decider), Node 5 (verifier)
clinical_report	Node 3 (reasoning)	Node 4 (decider), Node 5 (verifier)
case_understanding	Node 1 (understand)	Node 3 (reasoning), Node 5 (verifier)
answer, rationale	Node 4 (decider)	overwritten by Node 5, if present (V4/V5); Node 6 reads answer to check correctness (V5)

Each field is written once and read straight off state by every node downstream — no agent, no store, no extra LLM call.

No cross-question (episodic) memory in this table — every row lives only within one thread (one question).
